Traction Smart Cities Ecosystem

»» **TractionLive**

View real-time system status from your web browser or mobile device.

»» **TractionTravel**

Collect, analyze, and automate travel time data and alerts.

»» **TractionPriority**

Provide centralized priority for all modes of transportation.

»» **TractionMetrics**

Visualize performance data with streamlined dashboards and reports.

»» **TractionConnect**

Share and receive connected vehicle data and traveler information messages.

»» **TractionWorkflow**

Manage assets, inventory, and work order tasks.

Performance

- Throughput

Throughput is a measure of efficiency. It is meant to represent the maximum number of vehicles served on all phases at an intersection.

It is calculated as the highest 15-minute volume in a day at an intersection, converted to an hourly volume. Volumes come from high-resolution event logs from the controller, which are stored in the ATSPM database. All detectors used for volume counts are used in the throughput calculation for an intersection. It includes Tuesdays, Wednesdays and Thursdays only.

Detectors used for volume counts are selected based on a hierarchy, as there may be more than one detector in a given lane. For each lane, the detector with the highest count priority is selected for the count-based metrics. The priority scale is as follows:

- Exit
- Advanced Count
- Lane-by-lane Count

- Arrivals on Green

Arrivals on Green (AOG) is a measure of coordination. A high percentage of arrivals on green would be the result of good offsets and should be correlated with fewer stops and less delay.

AOG is calculated as the total number of vehicles arriving on green light divided by the total number of arrivals. It is based on primary street through-phases, limited to peak periods (6am-10am, 3pm-7pm) on Tuesdays, Wednesdays and Thursdays.

The calculation uses detector data from Advance Count or Exit detectors, as configured in ATSPM. For advance detectors, the time of arrival at the intersection is adjusted for the setback distance and speed limit, both of which are configured in ATSPM.

Volume & Equipment

- Detector Uptime

Detector Uptime is a measure of state-of-good-repair, which may be correlated to other performance measures since failed detectors may negatively affect performance.

Based on hourly volumes by detector, detector is evaluated according to three criteria:

- Volume too high
- Volume erratic (too much change from one hour to the next)
- Volume flatlined (no change in volume between successive time periods).

Each detector is evaluated over each day. A detector is considered if failed for the day if any of the following conditions apply:

- There is a streak of at least 5 hours where the volume does not change, disregarding the hours before 5am.
- At least 5 hours in the day have a volume exceeding 2000 vehicles
- The mean absolute deviation (average magnitude difference between successive hours) is greater than 500.

- + Pedestrian Pushbutton Uptime
- + Communications Uptime
- + Events Reported, Resolved, Outstanding
- + RTOP Activity Logs
